## UNIT TESTING OF ONEWIRE LIBRARY AND UART LIBRARY REVISION 1.1

## **UART LIBRARY TESTING**

The module located in /src/firmware/UART\_LIBRARY is a module for controlling input and output from Arduino/AVR devices used in the project. It has functionality for relaying individual bytes from the Arduino, as well as storing the data in a buffer(s) to send in larger batches. A flush function was implemented to flush a buffer in case the input was no longer desired. Lastly, the ability to switch between up to four output channels was implemented.

Testing was conducted with CoolTerm serial communicator and an Arduino Mega. In the Arduino's programming, strings were printed using the UART printf function, which were then received by CoolTerm. If the beginning and received strings are identical, that was the desired result. To test a buffer, small buffer sizes were used, with a counter being printed. If the counter corresponded to the buffer size, the buffer could be considered working. To test the flush function, a buffer was flushed; if all data inside has been cleared, the flush performed as desired. To test the ability to switch between output channels, it was a simple matter to print to a location then received by CoolTerm.

## Equivalence Classes used:

The size of the buffer is an equivalence class-- it can be assumed that the buffer will perform the same with a large size (up to the size of free, addressable program memory) as well as a small size.

## **ONEWIRE LIBRARY TESTING**

The module located in /src/firmware/One\_Wire\_Library is a driver for the ds18b20 temperature sensor. It provides functionality for sending temperature data, receiving configuration data, as well as the implementation of a custom floating point function.

Testing was conducted by sending data to the sensor through the UART library. Then, using serial communication software, (in this case, CoolTerm was used) the output of the sensor was analyzed to see if the data received matched the intended result. Secondly, corner cases were used to simulate temperatures beyond the specification of the sensor.

Equivalence Classes passed into the sensor:

Any valid temperature reading will return a valid result; any invalid data will return -9999.99.
